Operating Systems (OS) Introduction & System Calls

Prof. Eun-Seok Ryu (esryu@skku.edu)

Multimedia Computing Systems Laboratory http://mcsl.skku.edu

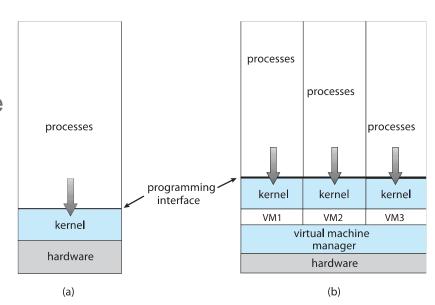

Department of Immersive Media Engineering
Department of Computer Education
Sungkyunkwan University (SKKU)

Review: Operating Systems?

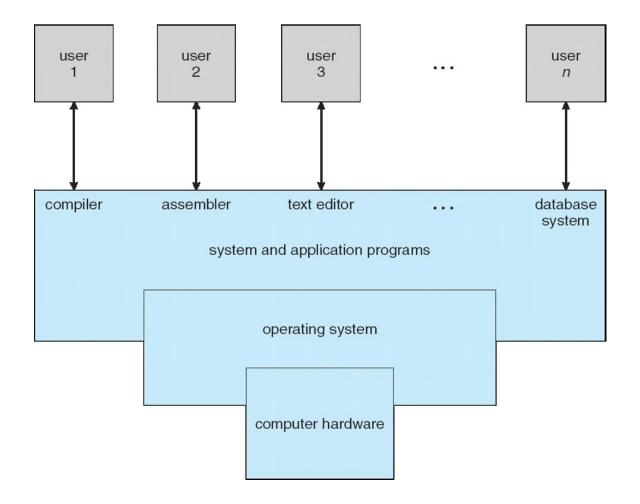

- What the operating systems (OS) is.
- The history of OS.
- How OS operates multiple applications at the same time?
 - Resource management and prioritization
 - Multimedia playing?
 - Selective scheduling
- What kinds of OS are developed?
- What could be a problem if there are many OS.
 - How the compatibility issue could be solved?
- Current OS developing direction.
- Report: <u>A survey on virtualization technologies.</u>

Four Components of a Computer System

Operating System (OS) Definition

OS is a resource allocator

Manages all resources

Decides between conflicting requests for efficient and fair resource use

OS is a control program

Controls execution of programs to prevent errors and improper use of the computer

No universally accepted definition

"Everything a vendor ships when you order an operating system" is a good approximation

But varies wildly

"The one program running at all times on the computer" is the kernel.

Everything else is either

a system program (ships with the operating system), or an application program.

Computer Startup

bootstrap program is loaded at power-up or reboot

Typically stored in ROM or EPROM, generally known as firmware

Initializes all aspects of system

Loads operating system kernel and starts execution

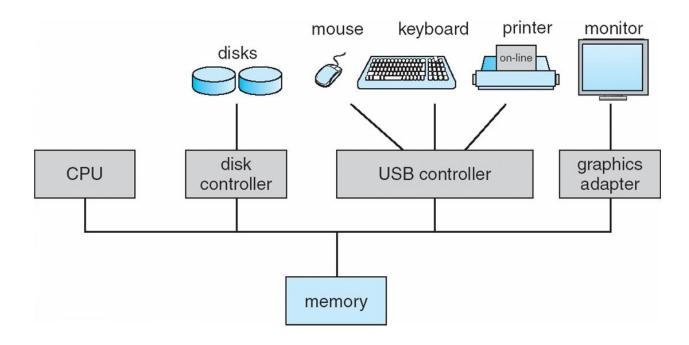

Computer System Organization

Computer-system operation

One or more CPUs, device controllers connect through common bus providing access to shared memory

Concurrent execution of CPUs and devices competing for memory cycles

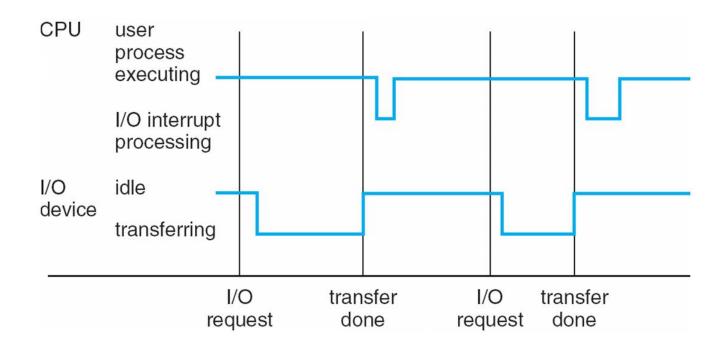

Interrupts and Interrupts Handling

Interrupts

A trap or exception is a <u>software-generated interrupt</u> caused either by an error or a user request

An operating system is interrupt driven

I/O Structure

After I/O starts, control returns to user program only upon I/O completion

Wait instruction idles the CPU until the next interrupt

Wait loop (contention for memory access)

At most one I/O request is outstanding at a time, no simultaneous I/O processing

After I/O starts, control returns to user program without waiting for I/O completion

System call – request to the OS to allow user to wait for I/O completion

Device-status table contains entry for each I/O device indicating its type, address, and state

OS indexes into I/O device table to determine device status and to modify table entry to include interrupt

Interrupt Driven Hardware and Software

Hardware interrupt by one of the devices Software interrupt (exception or trap):

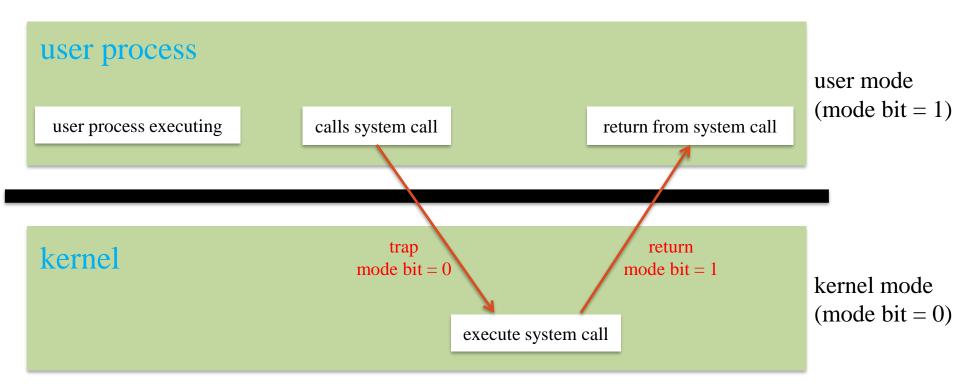

- Software error (e.g., division by zero)
- Request for operating system service
- Other process problems include infinite loop, processes modifying each other or the operating system

Transition from user to kernel mode

User mode and kernel mode

System Calls

Programming interface to the services provided by the OS

Typically written in a high-level language (C or C++)

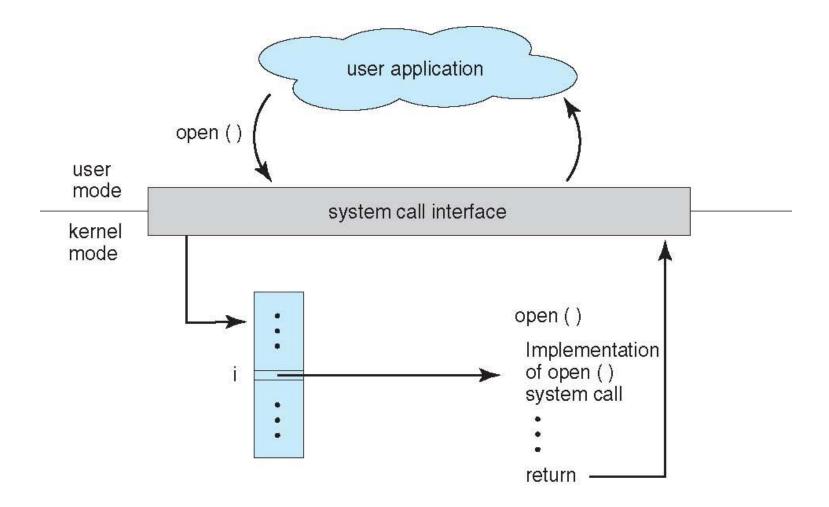

Mostly accessed by programs via a high-level **Application Programming Interface (API)** rather than direct system call use

Three most common APIs are Win32 API for Windows, POSIX API for POSIX-based systems (including virtually all versions of UNIX, Linux, and Mac OS X), and Java API for the Java virtual machine (JVM)

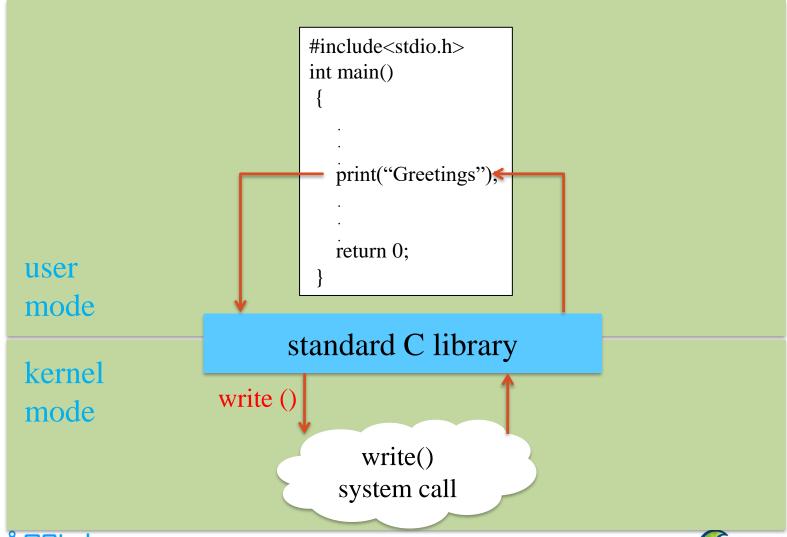

API – System Call – OS Relationship

Standard C Library Example

C program invoking printf() library call, which calls write() system call

Example of How System Calls are Used

System call sequence to copy the contents of one file to another file

source file

destination file

Example System Call Sequence

Acquire input file name

Write prompt to screen

Accept input

Acquire output file name

Write prompt to screen

Accept input

Open the input file

if file exists, abort

Loop

Read from input file

Write to output file

Until read fails

Close output file

Write completion message to screen

Terminate normally

Types of System Calls (1/2)

File management
create file, delete file
open, close file
read, write, reposition
get and set file attributes

Device management
request device, release device
read, write, reposition
get device attributes, set device attributes
logically attach or detach devices

Types of System Calls (2/2)

Information maintenance

get time or date, set time or date get system data, set system data get and set process, file, or device attributes

Communications

create, delete communication connection send, receive messages if message passing model to host name or process name

From client to server

Shared-memory model create and gain access to memory regions transfer status information attach and detach remote devices

Protection

Control access to resources
Get and set permissions

Allow and deny user access

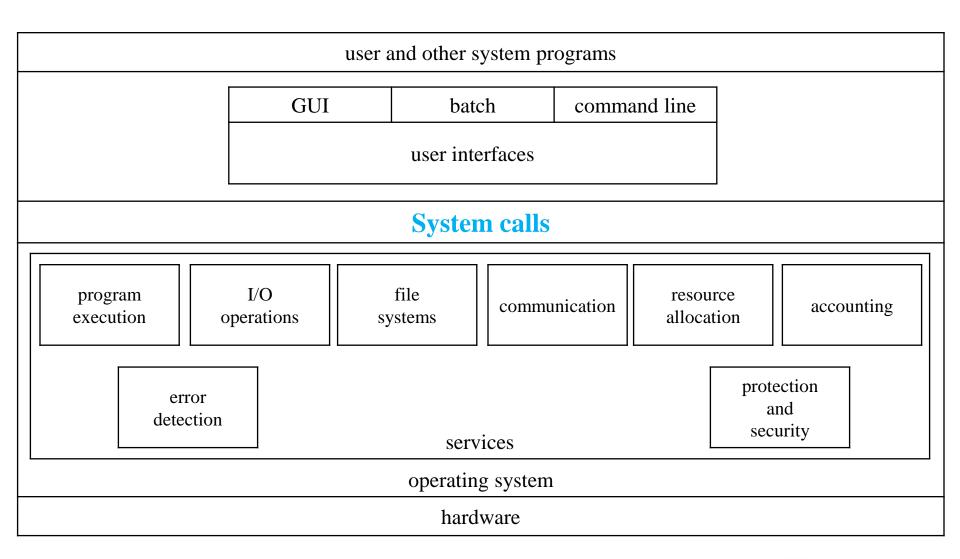

Examples of Windows and Unix System Calls

	Windows	Unix
Process Control	CreateProcess() ExitProcess() WaitForSingleObject()	fork() exit() wait()
File Manipulation	CreateFile() ReadFile() WriteFile() CloseHandle()	open() read() write() close()
Device Manipulation	SetConsoleMode() ReadConsole() WriteConsole()	ioctl() read() write()
Information Maintenance	GetCurrentProcessID() SetTimer() Sleep()	getpid() alarm() sleep()
Communication	CreatePipe() CreateFileMapping() MapViewOfFile()	pipe() shmget() mmap()
Protection	SetFileSecurity() InitlializeSecurityDescriptor() SetSecurityDescriptorGroup()	chmod() umask() chown()

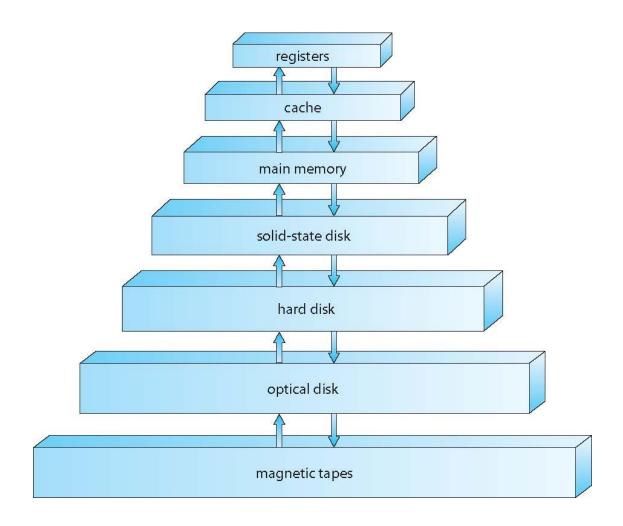

A view of Operating System Services

Storage-Device Hierarchy

Caching

- Important principle, performed at many levels in a computer (in hardware, operating system, software)
- Information in use copied from slower to faster storage temporarily
- Faster storage (cache) checked first to determine if information is there
 - If it is, information used directly from the cache (fast)
 - If not, data copied to cache and used there
- Cache smaller than storage being cached
 - Cache management important design problem
 - Cache size and replacement policy

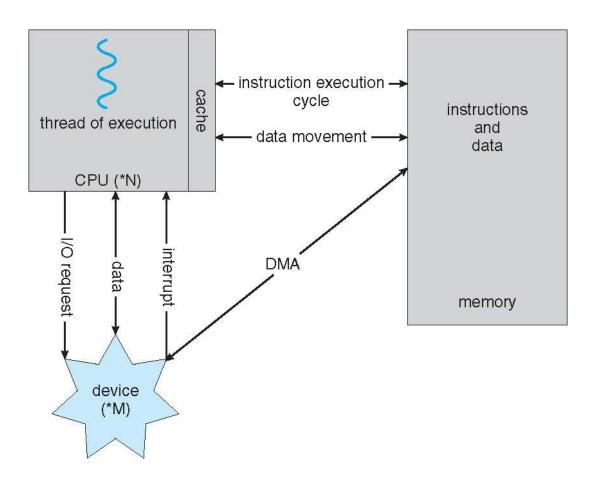

Direct Memory Access (DMA) Structure

- Used for high-speed I/O devices able to transmit information at close to memory speeds
- Device controller transfers blocks of data from buffer storage <u>directly</u> to <u>main memory without CPU</u> <u>intervention</u>
- Only one interrupt is generated per block, rather than the one interrupt per byte

How a Modern Computer Works

A von Neumann architecture

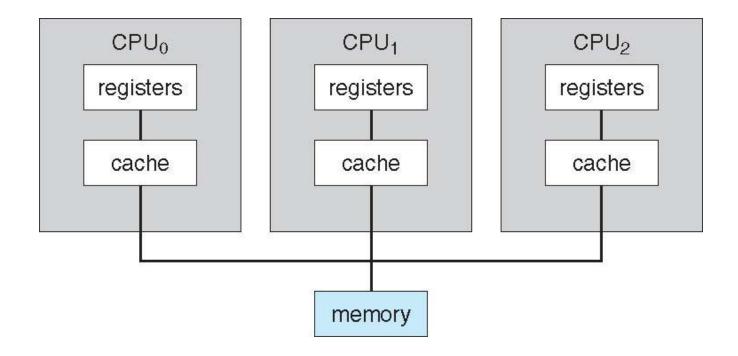

Computer-System Architecture

- Most systems use a single general-purpose processor
 - Most systems have special-purpose processors as well
- Multiprocessors systems growing in use and importance
 - Also known as parallel systems, tightly-coupled systems
 - Advantages include:
 - 1. Increased throughput
 - 2. Economy of scale
 - 3. Increased reliability graceful degradation or fault tolerance
 - Two types:
 - Asymmetric Multiprocessing each processor is assigned a specie task.
 - 2. Symmetric Multiprocessing each processor performs all tasks

Symmetric Multiprocessing Architecture

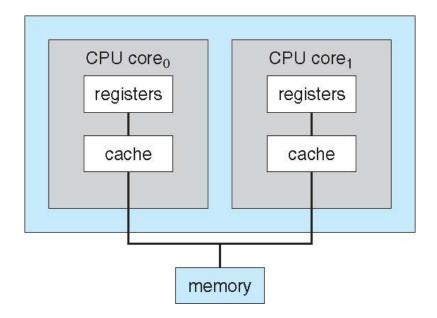

A Dual-Core Design

- Multi-chip and multicore
- Systems containing all chips
 - Chassis containing multiple separate systems

Operating System Structure

- Multiprogramming (Batch system) needed for efficiency
 - Single user cannot keep CPU and I/O devices busy at all times
 - Multiprogramming organizes jobs (code and data) so CPU always has one to execute
 - A subset of total jobs in system is kept in memory
 - One job selected and run via job scheduling
 - When it has to wait (for I/O for example), OS switches to another job
- Timesharing (multitasking) is logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating interactive computing
 - Response time should be < 1 second
 - Each user has at least one program executing in memory ⇒process
 - If several jobs ready to run at the same time ⇒ CPU scheduling
 - If processes don't fit in memory, swapping moves them in and out to run
 - Virtual memory allows execution of processes not completely in memory

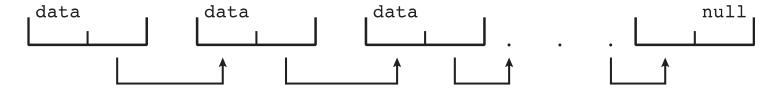

Operating-System Operations

- Interrupt driven (hardware and software)
 - Hardware interrupt by one of the devices
 - Software interrupt (exception or trap):
 - Software error (e.g., division by zero)
 - Request for operating system service
 - Other process problems include infinite loop, processes modifying each other or the operating system
- Dual-mode operation allows OS to protect itself and other system components
 - User mode and kernel mode
 - Mode bit provided by hardware
 - Provides ability to distinguish when system is running user code or kernel code
 - Some instructions designated as privileged, only executable in kernel mode
 - System call changes mode to kernel, return from call resets it to user
- Increasingly CPUs support multi-mode operations
 - i.e. virtual machine manager (VMM) mode for guest VMs

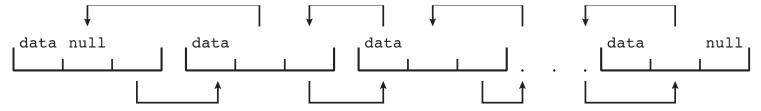

Kernel Data Structures

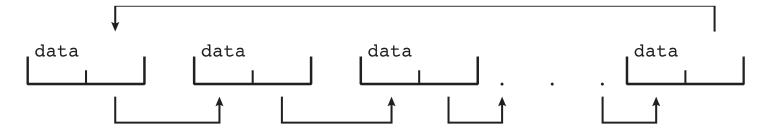

- Many similar to standard programming data structures
- Singly linked list

Doubly linked list

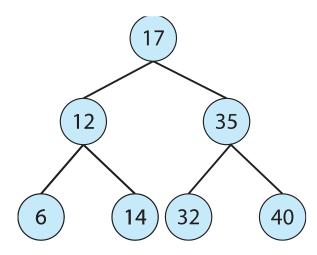

Circular linked list

Kernel Data Structures

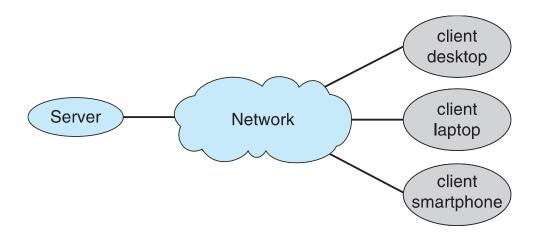

- Binary search tree
 - left <= right</pre>
 - Search performance is O(n)
 - Balanced binary search tree is O(lg n)

Computing Environments – Client-Server

- Client-Server Computing
 - Dumb terminals supplanted by smart PCs
 - Many systems now servers, responding to requests generated by clients
 - Compute-server system provides an interface to client to request services (i.e., database)
 - File-server system provides interface for clients to store and retrieve files

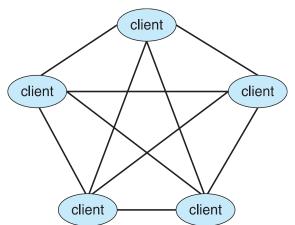

Computing Environments - Peer-to-Peer

- Another model of distributed system
- P2P does not distinguish clients and servers
 - Instead all nodes are considered peers
 - May each act as client, server or both
 - Node must join P2P network
 - Registers its service with central lookup service on network, or
 - Broadcast request for service and respond to requests for service via discovery protocol

 Examples include Napster and Gnutella, Voice over IP (VoIP) such as Skype

Computing Environments – Cloud Computing

- Cloud computing environments composed of traditional OSes, plus VMMs, plus cloud management tools
 - Internet connectivity requires security like firewalls
 - Load balancers spread traffic across multiple applications

Computing Environments – Real-Time Embedded Systems

- Real-time embedded systems most prevalent form of computers
 - Vary considerable, special purpose, limited purpose
 OS, real-time OS
 - Use expanding
- Many other special computing environments as well
 - Some have OSes, some perform tasks without an OS
- Real-time OS has well-defined fixed time constraints
 - Processing must be done within constraint
 - Correct operation only if constraints met
